

Midterm Exam #2 Formula Sheet

Put-call parity theorem (assuming no dividends; options are European):

$$c + Ke^{-rn\delta t} = p + S,$$

where

δt = the length of a timestep; e.g., if the timestep is one year, then $\delta t = 1$.

n = the number of timesteps until expiration;

c = value of a call option with an exercise price of K and n timesteps until expiration;

p = value of a put option with an exercise price of K and n timesteps until expiration;

r = the annualized riskless rate of interest; and

S = the value of the underlying asset.

Risk neutral probability of an “up” move: $q = \frac{e^{r\delta t} - d}{u - d}$, where

q = the risk neutral probability of an “up” move;

$u = 1$ plus the rate of return from an “up” move; and

$d = 1$ plus the rate of return from a “down” move.

Risk Neutral Valuation Formula (for a 1 timestep call or put option):

$$f = e^{-r\delta t}[qf_u + (1 - q)f_d],$$

where

f_u = the value of the option at the u node; and

f_d = the value of the option at the d node.

Risk Neutral Valuation Formula for an n timestep European call option (AKA the “Cox-Ross-Rubinstein” model):

$$c = e^{-rn\delta t} \left[\sum_{j=a}^n \left(\frac{n!}{j!(n-j)!} \right) q^j (1-q)^{n-j} (u^j d^{n-j} S - K) \right],$$

where $a =$ the smallest integer value $> \ln(K/Sd^n)/\ln(u/d)$.

Normal Probability Distribution for the continuously compounded rate of return

$$\ln(S_T/S) \sim N((\mu - .5\sigma^2)T, \sigma^2 T),$$

where

$\ln(S_T/S)$ = T -period continuously compounded rate of return;

μ = expected return (per unit of time) in the absence of uncertainty;

σ = stock price volatility (per unit of time);

$(\mu - .5\sigma^2)T$ = the mean of $\ln(S_T/S)$; and

$\sigma^2 T$ = the variance of $\ln(S_T/S)$.

Standard Normal Distribution Function
